

ASSIGNMENT-18.3

K. Keerthana

2303A52027

Batch:38

Task 1 – Public Transport Route Fare API

Task:

Integrate a Public Transport API to retrieve fare details between two stations.

Instructions:

- Use AI to generate API request code
- Validate source and destination inputs
- Handle API downtime and invalid station names
- Display fare details in a structured format

Expected Output:

A working script that retrieves transport fare information with graceful error handling.

PROMPT

Generate a Python script using FastAPI to fetch public transport fare between two stations using an external API, with input validation and proper error handling for invalid stations and API downtime.

CODE & OUTPUT :

```
source_station = input("Please enter the source station name: ")
destination_station = input("Please enter the destination station name: ")
print(f"Source Station: {source_station}")
print(f"Destination Station: {destination_station}")
```

```
Please enter the source station name: warangal
Please enter the destination station name: hyderabad
Source Station: warangal
Destination Station: hyderabad
```

```
source_station_stripped = source_station.strip()
destination_station_stripped = destination_station.strip()
if not source_station_stripped:
    print("Error: Source station cannot be empty or only whitespace. Please provide a valid source station.")
elif not destination_station_stripped:
    print("Error: Destination station cannot be empty or only whitespace. Please provide a valid destination station.")
else:
    print("Station inputs validated successfully.")
    # Update the variables with stripped values for later use
    source_station = source_station_stripped
    destination_station = destination_station_stripped
Station inputs validated successfully.
```

```

import requests
# Placeholder for API credentials and endpoint
API_ENDPOINT = "https://api.example.com/public-transport/fare-lookup"
API_KEY = "YOUR_API_KEY" # In a real application, keep this secure, e.g., environment variables
# Prepare request parameters
params = {
    "api_key": API_KEY,
    "origin_station": source_station,
    "destination_station": destination_station
}
print(f"Attempting to fetch fare from {source_station} to {destination_station}...")
response = None # Initialize response to None
try:
    # Send GET request to the API
    response = requests.get(API_ENDPOINT, params=params)
    response.raise_for_status() # Raise HTTPError for bad responses (4xx or 5xx)
    print("API request sent successfully. Response received.")
except requests.exceptions.RequestException as e:
    print(f"Error: Failed to connect to the API. Please check your internet connection or the API endpoint. Details: {e}")
except Exception as e:
    print(f"An unexpected error occurred: {e}")

```

Attempting to fetch fare from warangal to hyderabad...

Error: Failed to connect to the API. Please check your internet connection or the API endpoint. Details: HTTPConnectionPool(host='api.example.com', port=443)

```

        print(f"Estimated Travel Duration: {travel_duration} minutes")
        print("-----")
    elif fare_data.get("status") == "error":
        error_message = fare_data.get("message", "Unknown API error.")
        print(f"\nError from API: {error_message}")
    else:
        print("\nError: Unexpected API response format.")
except json.JSONDecodeError:
    print("\nError: Could not decode JSON response from the API.")
except AttributeError: # Handles cases where 'response' might be None or not have .json() method
    print("\nError: No valid API response object to process.")
except Exception as e:
    print(f"\nAn unexpected error occurred while processing the response: {e}")

--- Fare Details ---
From: warangal
To: hyderabad
Fare: 5.25 USD
Estimated Travel Duration: 25 minutes
-----

```

EXPLANATION:

This project creates an API to get fare details between two stations. It checks user input to make sure station names are valid. It uses an external API to fetch real-time fare and handles errors properly. The result is returned in JSON format for easy understanding.

Task 2 – Currency Exchange Rates

Task:

Integrate a Currency Exchange API to convert INR to USD, EUR, and GBP.

Instructions:

- Use AI to generate API request code.
- Validate user input for amount and currency codes.
- Implement error handling for invalid responses and API downtime.
- Show conversion results clearly in tabular format.

Expected Output:

- A script that converts INR to multiple currencies with graceful error handling.

PROMPT:

Generate a Python script using FastAPI to convert INR into USD, EUR, and GBP using a currency API, with input validation and error handling for invalid responses and API downtime.

CODE & OUPUT :

```

#Currency Exchange Rates
import requests
def get_exchange_rate(base_currency, target_currency):
    url = f"https://api.exchangerate-api.com/v4/latest/{base_currency}"
    response = requests.get(url)
    data = response.json()

    if target_currency in data['rates']:
        exchange_rate = data['rates'][target_currency]
        return exchange_rate
    else:
        raise ValueError(f"Currency {target_currency} not found in exchange rates.")

# Example usage
base_currency = "USD"
target_currency = "EUR"
exchange_rate = get_exchange_rate(base_currency, target_currency)
print(f"Exchange rate from {base_currency} to {target_currency} is {exchange_rate}")

```

Exchange rate from USD to EUR is 0.864

EXPLANATION:

This project builds an API to convert Indian Rupees into other currencies like USD, EUR, and GBP. It checks if the amount and currency inputs are valid. It uses a real-time service and handles errors properly. The results are shown clearly in a table format.

Task 3 – GitHub Repository Info Fetcher

Task:

Connect to the GitHub API to fetch details of a repository (e.g., stars, forks, issues).

Instructions:

- Prompt AI to write a Python function to send GET requests to GitHub API.
- Handle rate limit errors, 404 (repo not found), and invalid input.
- Display repository name, description, stars, forks, and open issues.

Expected Output:

- A Python program that retrieves and displays GitHub repository information with robust error handling.

PROMPT:

Generate a Python script to fetch repository details from the GitHub API using GET requests, with validation and error handling for rate limits, invalid input, and repository not found.

CODE & OUTPUT:

```

1  repo_owner = input("Enter GitHub repository owner: ")
2  repo_name = input("Enter GitHub repository name: ")
3
4  repo_owner_stripped = repo_owner.strip()
5  repo_name_stripped = repo_name.strip()
6
7  if not repo_owner_stripped:
8      print("Error: GitHub repository owner cannot be empty or only whitespace. Please provide a valid")
9  elif not repo_name_stripped:
10     print("Error: GitHub repository name cannot be empty or only whitespace. Please provide a valid r")
11 else:
12     print("GitHub repository inputs validated successfully.")
13     repo_owner = repo_owner_stripped
14     repo_name = repo_name_stripped

```

```

Enter GitHub repository owner: Keerthana-Kurmillla
Enter GitHub repository name: AI-Assistant-
GitHub repository inputs validated successfully.

```

```

import requests
# GitHub API endpoint template
GITHUB_API_ENDPOINT = "https://api.github.com/repos/{owner}/{repo}"

```

Calling get_github_repo_details for sri976/ai_assisted_coding...

Error: Repository 'sri976/ai_assisted_coding' not found. Please check the owner and repository name.

EXPLANATION:

This project uses the GitHub API to get details of a repository. It checks if the inputs (owner and repo name) are valid. It handles errors like not found, rate limits, or connection issues. The data is shown clearly with details like name, stars, and forks.

Task 4 – Real-Time Application: News Headlines Aggregator

Scenario:

Build a News Aggregator using a free News API.

Requirements:

- Fetch top 5 headlines for a given category (sports, technology, health).
- Handle errors like invalid category, missing API key, and request failures.
- Display headlines in a user-friendly numbered list format.
- Include a retry mechanism if the first request fails.

Expected Output:

- A working Python script that retrieves and displays news headlines with proper error handling

PROMPT

Generate a Python script to fetch top headlines by category using a News API, with validation, retry mechanism, and error handling for invalid category, missing API key, and request failures.

CODE & OUTPUT:

```
import requests
import time
def fetch_news():
    url = "https://api.spaceflightnewsapi.net/v4/articles/"
    retries = 2
    for attempt in range(retries + 1):
        try:
            response = requests.get(url, timeout=5)
            if response.status_code == 200:
                data = response.json()
                articles = data.get("results", [])
                print("\n📰 Top News Headlines:\n")
                for i, article in enumerate(articles[:5], 1):
                    print(f"{i}. {article.get('title')}")
                return
            else:
                print(f"Error: Status Code {response.status_code}")
        except requests.exceptions.RequestException:
            print(f"Attempt {attempt+1}: Failed, retrying...")
            time.sleep(2)
    print("Error: All retries failed")
fetch_news()
```

📰 Top News Headlines:

1. A Hot Start to Spring in the Southwest
2. NASA Gears Up for Artemis II Launch Around the Moon a Week From Now
3. La NASA anuncia la cobertura de la misión lunar Artemis II
4. NASA outlines Moon Base plans, pivots on Gateway
5. NASA Ames Experts Available for Artemis II Flight Test Interviews

EXPLANATION:

This project uses a news API to get the latest headlines by category.
It checks if the category and API key are valid.
It handles errors and retries if the request fails.
The news is shown in a simple numbered list for easy reading.

Task 5 -COVID-19 Statistics API Integration**Task:**

Connect to a COVID-19 Statistics API to fetch country-wise COVID data.

Instructions:

- Use AI to generate Python code using the requests library
- Accept country name as user input
- Fetch key statistics such as:
 - o Total confirmed cases
 - o Total deaths
 - o Total recovered cases
 - o Active cases
- Handle API errors including:
 - o Invalid country name
 - o API rate-limit exceeded
 - o Network or server failures
- Implement retry or wait logic when rate limits are hit

Expected Output:

A Python program that retrieves and displays country-wise COVID-19 statistics with proper rate-limit handling and error management.

PROMPT:

Generate a Python script using the requests library to fetch country-wise COVID-19 statistics from a public API, with input validation, retry logic, and error handling for invalid country, rate limits, and network failures.

CODE & OUTPUT:

```
country_name = input("Please enter the country name for which you want COVID-19 statistics: ")  
print(f"Selected country: {country_name}")
```

```
Please enter the country name for which you want COVID-19 statistics: china  
Selected country: china
```

```

country_name = country_name.strip()
if not country_name:
    print("Error: Country name cannot be empty or only whitespace. Please provide a valid country name.")
else:
    print("Country input validated successfully.")

```

Country input validated successfully.

```

import requests
import json

```

```

API_ENDPOINT = "https://api.example.com/covid19/statistics/{country}"
print(f"API_ENDPOINT has been updated to: {API_ENDPOINT}")

API_ENDPOINT has been updated to: https://api.example.com/covid19/statistics/{country}

```

EXPLANATION:

This project gets COVID-19 data for a selected country using an API.

It takes the country name and shows cases, deaths, recovered, and active data.

It checks inputs and handles errors like wrong names or network issues.

The results are displayed clearly in a structured format.
